

Comparative Analysis of Optical Deception: Solar Observer Horizons vs. Black Hole Light Entrapment

Researcher: Wasfi Ahmed Mohammed Al-Shhada

Project ID: WAM-2025-DISTINCT-02

December 24, 2025

1 Introduction

According to the unified theory of **Wasfi Al-Shhada**, it is imperative to distinguish between two distinct phenomena of optical deception to prevent theoretical overlap.

2 Phenomenon A: The Fake Solar Horizon (Observer-Based)

The solar horizon viewed from Earth is a **"Fake Visual Horizon"**. This is a relative deception dependent on the observer's position and the phase vaporization of photons as they hit the atmospheric and gravitational threshold of the observer's frame.

3 Phenomenon B: Black Hole Light Entrapment (Fundamental Deception)

Unlike the solar horizon, light entrapment in black holes is a **"Fundamental Optical Deception"**. It is not caused by gravity preventing escape, but by the absolute conversion of photons into **Electron Vaporization** at the event horizon, leading to **Electron Enshrinement (T'abeen)**.

4 Structural Comparison Table

Feature	Fake Solar Horizon	Black Hole Entrapment
Nature	Relative/Observer-dependent	Absolute/Fundamental Phase Shift
Mechanism	Visual Deception of Distance	Visual Deception of Confinement
State	Partial Phase Vaporization	Total Electron Enshrinement (T'abeen)
Medium	Solar-Atmospheric Threshold	Event Horizon Boundary

Table 1: Comparison between observer-based deception and fundamental entrapment.

5 Mathematical Distinction

The "Deception Factor" (D) for the solar horizon is calculated based on latitude:

$$D_{sun} = \arctan(n_{depth}) \cdot \cos(\phi) \quad (1)$$

Whereas the "Vaporization Rate" for black holes is an intrinsic property of the horizon boundary:

$$\frac{dN_e}{dt} = f_{QPS}(\text{Fundamental Energy State}) \quad (2)$$
