## Abstract

This document presents the official mathematical formulation of the **Shhada Phase-Shift Constant** ( $\mathcal{V}_c = \frac{1}{3}$ ) within the Structural Identity Theory (SIT-WAM) framework. This critical threshold governs the abrupt transition of matter from structural cohesion to absolute electron vaporization (*T'abeen*) and localized space elimination, establishing the sole driver of cosmic and local expansion without dark energy.

## 1. The Core Master Equation

The total structural energetic and behavioral state function  $\Xi(\mathcal{V})$  of a collapsing structural volume fraction  $\mathcal{V}$  is governed by the following discontinuous phase-shift formulation:

$$\Xi(\mathcal{V}) = \Theta\left(\mathcal{V} - \frac{1}{3}\right) \cdot \mathcal{S}_c(\mathcal{V}) + \Theta\left(\frac{1}{3} - \mathcal{V}\right) \cdot \left[\Lambda_{\text{exp}} \cdot \exp\left(\alpha\left(\frac{1}{3} - \mathcal{V}\right)\right)\right] \quad (1)$$

**Where:**

- $\Xi(\mathcal{V})$  is the **Total Structural Energetic Behavior State**.
- $\mathcal{V}$  is the instantaneous structural volume fraction ( $0 \leq \mathcal{V} \leq 1$ ).
- $\mathcal{V}_c = \frac{1}{3}$  is the **Shhada Phase-Shift Constant** (The One-Third Prefix Boundary).
- $\Theta(x)$  is the Heaviside step function, dictating the operational regime before and after the collapse.
- $\mathcal{S}_c(\mathcal{V})$  is the **Structural Cohesion Function**, defining stable mass-energy interactions governed by the Shhada constant ( $\Psi$ ) when the 2/3 gluon energy envelope is active:

$$\mathcal{S}_c(\mathcal{V}) = \sum_{i=1}^3 (Q_i \cdot \Phi_e) - \Delta E_{\text{mourning}} \quad (2)$$

- $\Lambda_{\text{exp}}$  is the **Space Elimination Factor** triggered at the event horizon boundary due to absolute electronic obituary (*T'abeen*), formulated as:

$$\Lambda_{\text{exp}} = \oint_{\text{Event Horizon}} \sigma(T'abeen) dV \quad (3)$$

- $\alpha$  is the **Exponential Vacancy Acceleration Coefficient** representing the rapid annihilation of the physical carrier medium ( $e^- \rightarrow 0$ ).

## 2. Physical and Chemical Implications

When the collapsing mass reaches the limit  $\mathcal{V} \rightarrow \frac{1}{3}^+$ , the 2/3 energy envelope composed of gluon energy from nuclear shell distortions is completely depleted. At the exact boundary  $\mathcal{V} = \frac{1}{3}$ , the system undergoes a critical phase transition:

1. **Physical Regime** ( $\mathcal{V} \leq \frac{1}{3}$ ): The structural vacancy triggers an instantaneous localized spatial expansion rate  $\lambda_{\text{exp}}$ , eliminating the necessity for arbitrary external cosmological constants or dark energy.
2. **Chemical Regime** ( $\mathcal{V} \leq \frac{1}{3}$ ): Total electron enshrinement eliminates valence electron carrier mediums, rendering traditional chemical bounds obsolete and reducing the system to pure topological energetic interactions.
